### Abstract

Statistical Curvature of Bradley Efron helps in comparing curved exponential family of distributions with corresponding exponential family of distribution. The analysis in curved family has been made easy by that concept. But suitable test procedures are unavailable for discrete curved exponent families. In this paper a suitable test procedure for Curved Poisson distribution is obtained

**Keywords:** Statistical curvature, curved exponential family, curved Poisson distribution, likelihood function..

### Introduction

Curved exponential family of distributions plays an important role in Statistics. But in case of inference on such distributions we have to face certain obstacles because curved exponential family does not have good statistical properties as the exponential family. Bradley Efron<sup>1</sup> has compared curved exponential family with exponential family introducing the concept of Statistical Curvature or Efron's Curvature. He has shown in his paper that families with small curvature enjoy good statistical properties of exponential family as exponential family has curvature zero. Moreover it can be shown that if one takes an example of a distribution from exponential family and deals it as a curved exponential family then the statistical curvature of such curved exponential family becomes exactly equal to zero. So, after finding the values of the involved parameter of a curved exponential distribution for which the statistical curvature attains small values, it can be concluded that for such values of the parameter, the test statistic of certain hypothesis is equivalent to that of the corresponding exponential family.

It has been found that some inference procedures are available fragmentally for continuous distributions of curved exponential family. But in case of discrete distributions from curved exponential family we cannot find such procedures for testing purpose.

Using statistical curvature this paper wants to find out a suitable test procedure for Curved Poisson distribution, in which the parameter of Poisson distribution involves another discrete distribution. In this paper Uniform distribution is taken as the involved discrete distribution.

### Some preliminary discussions regarding this topic

**Definition 2.1 (Curved Exponential Family of Distributions):** Let  $X = (X_1, X_2, \dots, X_d)$  have a distribution  $P_\theta$ ,  $\theta \in \Theta \subseteq \mathbb{R}^q$ .

Suppose  $P_\theta$  has a density (pmf) of the form  $f(x|\theta) = \exp(\sum_{i=1}^k \eta_i(\theta)T_i(x) - \Psi(\theta))h(x)$ ,

where  $k > q$ . Then the family  $\{P_\theta, \theta \in \Theta\}$  is called curved exponential family<sup>2</sup>.

**Example 2.1:** A set of independently and identically distributed random variables which follow  $N(\theta, \theta^2)$ ,  $\theta$  is the unknown parameter involved in the distribution<sup>2</sup>. This is an example of a curved exponential distribution of continuous type.

**Example 2.2:** Suppose  $X$  and  $Y$  are two random variables such that

$$\begin{aligned} X &\sim B(n, p) \\ Y &\sim B(m, p^2) \end{aligned} \succ \text{independently}$$

where  $p$  is the unknown parameter involved in both the distributions<sup>2</sup>. This is an example of a curved exponential distribution of discrete type.

**Definition 2.2 (Statistical Curvature):** The concept of mathematical curvature extends to the curved lines in Euclidian k-space,  $E^k$ , say,  $\xi = \{\eta_\theta, \theta \in \Theta\}$ , where  $\Theta$  is the interval of real line. For each  $\theta$ ,  $\eta_\theta$  is a vector in  $E^k$  whose component wise derivatives with respect to  $\theta$  is denoted by

$$\dot{\eta}_\theta \equiv \left(\frac{\partial}{\partial \theta}\right) \eta_\theta \text{ and } \ddot{\eta}_\theta \equiv \left(\frac{\partial^2}{\partial \theta^2}\right) \eta_\theta$$

These derivatives are assumed to exist continuously in neighborhood of a value of  $\theta$  where it is wished to define the curvature. Let us also suppose that a  $k \times k$  symmetric non-negative definite matrix  $\Sigma_\theta$  is defined continuously in  $\theta$ .

Let  $M_\theta$  be a  $2 \times 2$  matrix, with entries denoted by  $v_{20}(\theta)$ ,  $v_{11}(\theta)$ ,  $v_{02}(\theta)$ , defined by

$$M_\theta \equiv \begin{pmatrix} v_{20}(\theta) & v_{11}(\theta) \\ v_{11}(\theta) & v_{02}(\theta) \end{pmatrix} \equiv \begin{pmatrix} \dot{\eta}_\theta' \Sigma_\theta \dot{\eta}_\theta & \dot{\eta}_\theta' \Sigma_\theta \ddot{\eta}_\theta \\ \ddot{\eta}_\theta' \Sigma_\theta \dot{\eta}_\theta & \ddot{\eta}_\theta' \Sigma_\theta \ddot{\eta}_\theta \end{pmatrix} \tag{2.1}$$

and let

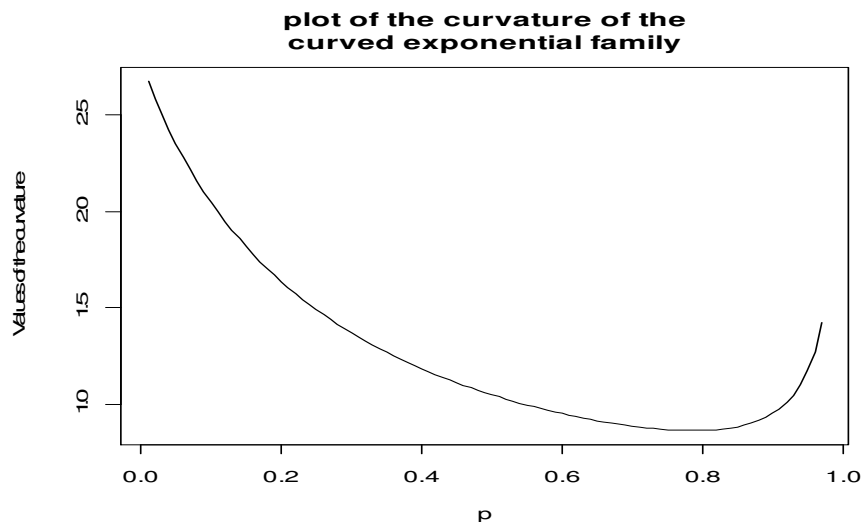

$$\gamma_\theta \equiv \left( |M_\theta| / v_{20}^3(\theta) \right)^{1/2} \tag{2.2}$$

Then  $\gamma_\theta$  is “the curvature of  $\xi$  at  $\theta$  with respect to inner product  $\Sigma_\theta$ ”.  $\gamma_\theta$  (given in 2.2), the statistical curvature of  $F$  at  $\theta$ , is the geometric curvature of  $\xi = \{\eta_\theta : \theta \in \Theta\}$  at  $\theta$  with respect to the covariance inner product  $\Sigma_\theta$  as defined in 2.1 and 2.2.

Here  $F$  will stand for the family of densities  $\{f_\theta(x) : \theta \in \Theta\}$ , our curved exponential family. Statistical Curvature is also known as Efron’s Curvature.

**Example 2.3:** The value of the statistical curvature of the distribution given in example 2.1 is  $= \left( \frac{2}{1331n} \right)^{1/2}$  for all possible values of  $\theta$ . That is for all possible values of  $\theta$  the statistical curvature have very small values. So, here the test procedure for  $\theta$  is equivalent to that of for exponential Normal distribution.

**Example 2.4:** The statistical curvature of the distribution given in example 2.2 is given in the following figure:

**Figure -1**  
 Figure -1, it is seen that for  $p=0.6$  to  $0.85$  the value of the curvature is small

A suitable test procedure for  $p$  in the distribution given in example 2.2 has been tried to be found out by Sanchayita Sadhu and Babulal Seal<sup>3</sup>.

**Definition 2. 3 (Curved Poisson Distribution):** A distribution is defined as Curved Poisson distribution if it is of the following form.

Suppose  $Z_i = z_i$ ,  $i = 1, 2, \dots, n$ .  $X_i$  are independent  $\text{Poi}(\lambda z_i)$  variables and  $Z_1, Z_2, \dots, Z_n$  have some joint p.m.f  $p(z_1, z_2, \dots, z_n)$ . It is implicitly assumed that each  $z_i > 0$  with probability 1. Then the joint p.m.f of  $(X_1, X_2, \dots, X_n, Z_1, Z_2, \dots, Z_n)$  is

$$f(x_1, x_2, \dots, x_n, z_1, z_2, \dots, z_n | \lambda) = e^{-\lambda \sum_{i=1}^n z_i + (\sum_{i=1}^n x_i) \log \lambda} \prod_{i=1}^n \frac{z_i^{x_i}}{x_i!} p(z_1, z_2, \dots, z_n) \quad 2.3$$

$$I_{x_1, \dots, x_n} \in N_0$$

$$I_{z_1, \dots, z_n} \in N_1$$

$N_0$  = set of non-negative integers,  $N_1$  = set of positive integers<sup>2</sup>.  
 This paper wants to find out a suitable test procedure for this distribution.

### Statistical Curvature of Curved Poisson distribution

Consider the Curved Poisson distribution as given in definition 2.3. Then its p.d.f. is given in equation 2.3.

Let  $Z_1, Z_2, \dots, Z_n$  are independently and identically distributed (i.i.d) as  $U(0,1)$  (discrete). Now comparing equation 2.3 with definition 1 i.e. comparing the p.d.f of Curved Poisson distribution with the form of Curved Exponential distribution, we get

$$\eta_1(\lambda) = -\lambda \quad \text{and} \quad \eta_2(\lambda) = \log \lambda \quad 3.1$$

$$T_1(X, Z) = \sum_{i=1}^n z_i \quad \text{and} \quad T_2(X, Z) = \sum_{i=1}^n x_i \quad 3.2$$

$$V(\sum_{i=1}^n z_i) = \sum_{i=1}^n V(Z_i) = \sum_{i=1}^n \frac{n^2 - 1}{12} = n \cdot \frac{n^2 - 1}{12} \quad 3.3$$

$$V(\sum_{i=1}^n x_i) = \sum_{i=1}^n V(X_i)$$

Now,  $V(X) = E(V(X|Z)) + V(E(X|Z)) = E(\lambda Z) + V(\lambda Z) = \lambda E(Z) + \lambda^2 V(Z)$

$$\therefore V(X) = \lambda \frac{n+1}{2} + \lambda^2 \frac{n^2 - 1}{12} \quad 3.4$$

$$\therefore \sum_{i=1}^n V(X_i) = \lambda \frac{n(n+1)}{2} + \lambda^2 \frac{n(n^2 - 1)}{12} \quad 3.5$$

Now covariance between  $T_1$  and  $T_2$  is to be found.

$$\text{cov}(\sum_{i=1}^n z_i, \sum_{i=1}^n x_i) = \sum_{i=1}^n \text{cov}(Z_i, X_i)$$

$$\text{cov}(Z_i, X_i) = E(Z_i X_i) - E(Z_i) E(X_i) \quad 3.6$$

$$E(Z_i X_i) = E_{Z_i} E_{X_i|Z_i}(Z_i X_i | Z_i)$$

Now,

$$= E_{Z_i}(\lambda Z_i^2)$$

$$= \lambda[V(Z_i) + E^2(Z_i)]$$

$$= \lambda(\frac{n^2 - 1}{12} + \frac{(n+1)^2}{4})$$

$$= \lambda \frac{4n^2 + 6n - 2}{12}$$

$$= \frac{\lambda(2n^2 + 3n - 1)}{6} \quad 3.7$$

$$E(X_i) = E_{Z_i} E_{X_i|Z_i}(X_i | Z_i) = \lambda \frac{n+1}{2} \tag{3.8}$$

∴ From 3.6,

$$\begin{aligned} \text{cov}(Z_i, X_i) &= \frac{\lambda(2n^2 + 3n - 1)}{6} - \lambda \frac{(n+1)^2}{4} \\ &= \lambda \frac{n^2 - 1}{12} \end{aligned} \tag{3.9}$$

$$\text{So, } \sum_{i=1}^n \text{cov}(Z_i, X_i) = \lambda \frac{n(n^2 - 1)}{12} \tag{3.10}$$

Therefore from 3.3, 3.5 and 3.10,

$$\Sigma_\lambda = \begin{pmatrix} \frac{n(n^2 - 1)}{12} & \frac{\lambda n(n^2 - 1)}{12} \\ \frac{\lambda n(n^2 - 1)}{12} & \lambda \frac{n(n+1)}{2} + n\lambda^2 \frac{n^2 - 1}{12} \end{pmatrix} \tag{3.11}$$

$$\text{and } \eta(\lambda) = \begin{pmatrix} -\lambda \\ \log \lambda \end{pmatrix} \tag{3.12}$$

$$\therefore \eta'(\lambda) = \begin{pmatrix} -1 \\ 1/\lambda \end{pmatrix} \quad \& \quad \ddot{\eta}(\lambda) = \begin{pmatrix} 0 \\ -1/\lambda^2 \end{pmatrix}$$

Using the concept of statistical curvature and 3.11, 3.12 the statistical curvature of Curved Poisson distribution can be found. In this paper statistical curvature of the Curved Poisson distribution for various values of n has been drawn through a programming in statistical software R.

The statistical curvatures for various values of n are given in figure-2, figure-3 and figure-4.

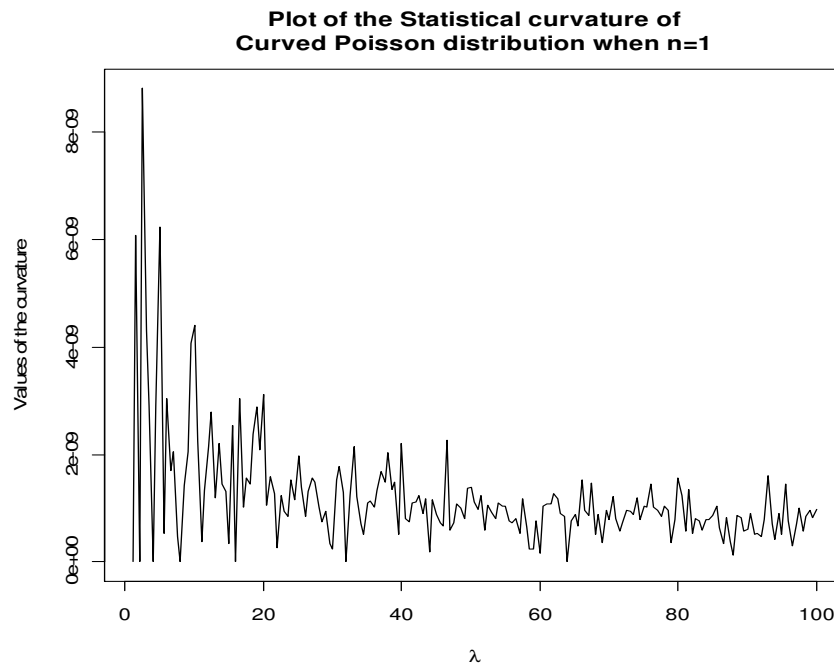

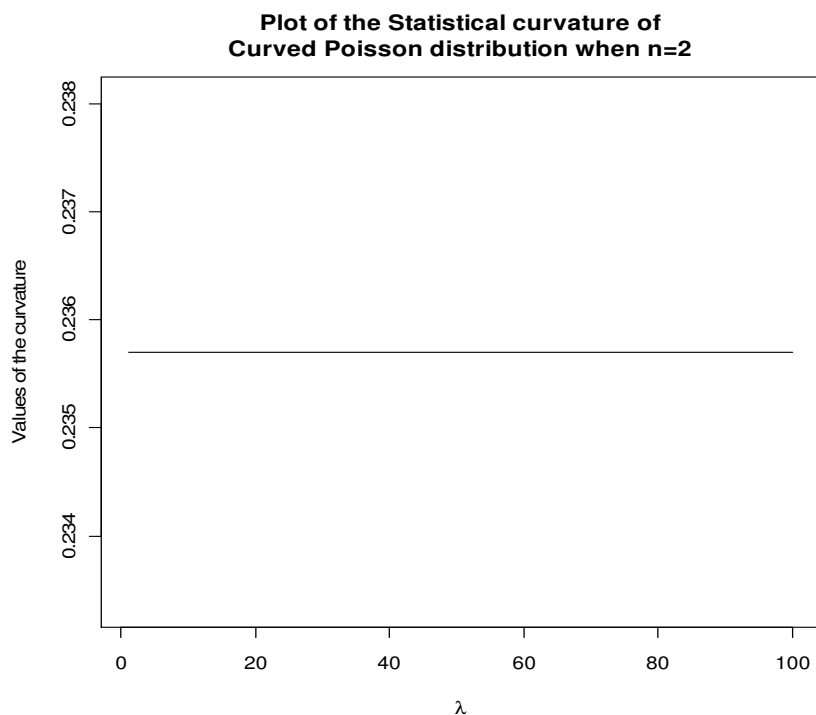

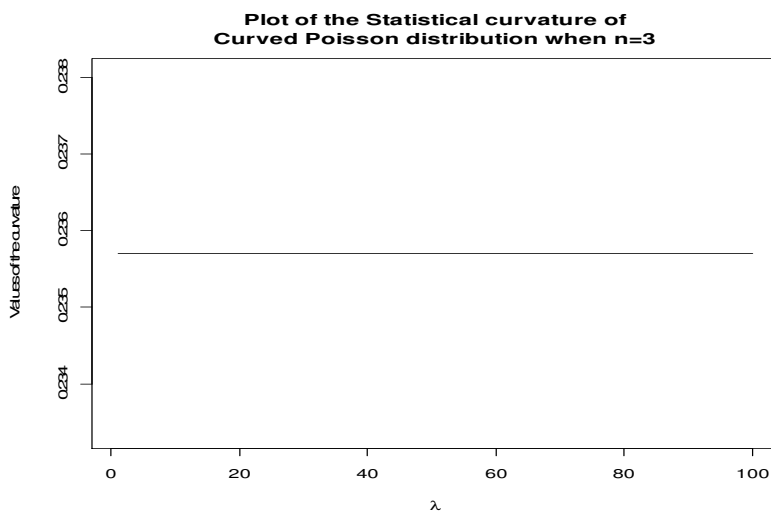

Figure -2

**Figure-3**

**Figure-4**

In this way the statistical curvature for this distribution can be found out for different values of  $n$ , where  $n$  is number of observations. From above pictures, it is seen that for  $n=1$ , for different values of parameter  $\lambda$  statistical curvature has different values; in case of other values of  $n$ , for different values of  $\lambda$  statistical curvatures have the same value. But in all cases the curvatures assign vary small values.

### **Inference of the Curved Poisson distribution**

There are test procedures for Poisson distribution which does not contain another discrete distribution with its parameter. As test procedure for Poisson distribution which contains another discrete distribution with its parameter are not available, to reach to any decision about  $\lambda$  of the above mentioned distribution, a test procedure should be found out.

To overcome this problem this paper would like to find out a test procedure to draw an inference about the null hypothesis.

From figure-2, figure-3 and figure-4, we see that the value of the curvature is small for all values of  $\lambda$ .

Now, let us demonstrate how to get the test method for such distribution. For example, let us work for getting test for  $H_0: \lambda_0 = 2$  vs.  $H_1: \lambda_0 \neq 2$ .

The test procedure is as follows:

Here  $X_i \sim \text{Poisson}(\lambda Z_i)$ , where  $Z_i \sim U(0,1)$ ,  $X_i$ 's and  $Z_i$ 's are independently and identically distributed.

Let  $X_1$  takes values  $1, 2, 3, \dots, k, \dots$  and  $Z_1 \sim U(0, 1, \dots, n)$ .

Then the probability that  $X_1$  takes a particular value  $k$  is given by

$$\frac{e^{-\lambda Z_i} (\lambda Z_i)^k}{k!} \tag{4.1}$$

Considering  $Z_1$ 's probability of taking a particular value, the joint probability becomes

$$\frac{1}{n+1} \frac{e^{-\lambda i} (\lambda i)^k}{k!} \tag{4.2}$$

Let  $X_1$  takes a particular value  $k$  and  $Z_1$  takes a particular value  $m$ .

$\therefore 0 \leq m \leq n$ .

Hence for an observation  $(x_1, z_1)$ , the likelihood function is

$$L(\lambda; x_1, z_1) = \frac{e^{-\lambda z_1} (\lambda z_1)^k}{k!} \times \frac{1}{n+1} \tag{4.3}$$

Let  $k$  be the fixed value of  $X_1$  and let  $m$  be the fixed value of  $Z_1$ . Then from (4.3),

$$\log L(\lambda) = -\lambda m + k \log(\lambda m) + c_1 \tag{4.4}$$

where  $c_1$  is a constant.

$$\therefore \frac{\partial \log L(\lambda)}{\partial \lambda} = -m + k \frac{m}{\lambda m} \tag{4.5}$$

Equating 4.5 to 0, we get

$$\frac{k}{\lambda} = m \Rightarrow \lambda = \frac{k}{m} \tag{4.6}$$

$$\begin{aligned} \therefore L(\hat{\lambda}) &= \frac{e^{-\frac{k}{m} m} \left(\frac{k}{m} m\right)^k}{k!} \frac{1}{n+1} \\ &= \frac{e^{-k} k^k}{k!} \frac{1}{n+1} \end{aligned} \tag{4.7}$$

$$\begin{aligned} \therefore \frac{L(\lambda_0)}{L(\hat{\lambda})} &= \frac{e^{-\lambda_0 m} (\lambda_0 m)^k}{e^{-k} k^k} \\ &= \left(\frac{\lambda_0 m}{k}\right)^k e^{-(\lambda_0 m + k)} \end{aligned} \tag{4.8}$$

So,  $H_0$  will be rejected if 4.8 is less than  $C$ , where  $C$  is a constant.

Now from 4.8

$$\left(\lambda_0 \frac{m}{k}\right)^k e^{-(\lambda_0 \frac{m}{k} + 1)k} = \left(\frac{\lambda_0 m e^{-(\lambda_0 \frac{m}{k} + 1)}}{k}\right)^k \tag{4.9}$$

$$= (te^{-(t+1)})^k \tag{4.10}$$

Here  $t = \frac{\lambda_0 m}{k}$ .

So, if  $f(t) = te^{-(t+1)}$  then for a fixed k,  $f(t) \uparrow$  if  $m < k/\lambda_0$  and  $f(t) \downarrow$  if  $m \geq k/\lambda_0$ . Hence from 4.8 and 4.10  $H_0$  will be rejected if  $4.10 < C$ .

Now,  $(te^{-(t+1)})^k < C$

$$m < \frac{k}{\lambda_0} t_0 \quad \text{if} \quad \lambda_0 \frac{m}{k} < 1 \tag{4.11a}$$

$\Leftrightarrow$

$$m \geq \frac{k}{\lambda_0} t_1 \quad \text{if} \quad \lambda_0 \frac{m}{k} \geq 1 \tag{4.11b}$$

Here  $t_0$  should be  $< 1$  and  $t_1$  should be  $> 1$ . 4.12

Therefore for a size  $\alpha$  test, for various values of k, the values of  $t_0$  and  $t_1$  to be found out such that

$$\sum_{m=\left[\frac{k}{\lambda_0} t_0\right]}^{\left[\frac{k}{\lambda_0} t_1\right]} e^{-\lambda_0 m} \frac{(\lambda_0 m)^k}{k!} \frac{1}{n+1} \geq 1 - \alpha \tag{4.13}$$

Now to achieve this, one way is to consider the following

$$\sum_{m=0}^{\left[\frac{k}{\lambda_0} t_0\right]} e^{-\lambda_0 m} \frac{(\lambda_0 m)^k}{k!} \frac{1}{n+1} \leq \alpha/2 \tag{4.14a}$$

$$\text{and} \quad \sum_{m=\left[\frac{k}{\lambda_0} t_1\right]}^n e^{-\lambda_0 m} \frac{(\lambda_0 m)^k}{k!} \frac{1}{n+1} \leq \alpha/2 \tag{4.14b}$$

For calculation purpose inequalities of 4.13a and 4.13b are

$$\sum_{m=0}^{\left[\frac{k}{\lambda_0} t_0\right]} e^{-\lambda_0 m} (\lambda_0 m)^k \leq \frac{\alpha(n+1)k!}{2} \tag{4.15a}$$

$$\text{and} \quad \sum_{m=\left[\frac{k}{\lambda_0} t_1\right]}^n e^{-\lambda_0 m} (\lambda_0 m)^k \leq \frac{\alpha(n+1)k!}{2} \tag{4.15b}$$

Considering condition (4.12) and using equations (4.15a) and (4.15b) the values of  $t_0$  and  $t_1$  have been found out taking  $\alpha=0.01$ . For this purpose, this paper uses an R program. The following tables will give the values of  $t_0$  and  $t_1$  from which one can reach to the decision.

Tables to find the values of  $t_0$  corresponding to different values of k and n:

**Table-1**  
 Table to find the values of  $t_0$  corresponding to different values of k and n=1

When n=1				
Values of k	Values of R.H.S. of (4.15a)	Values of m (= $kt_0/\lambda_0$ ) for which L.H.S. is just > R.H.S.	Values of L.H.S. which is just > R.H.S.	Values of $t_0$ (= $m\lambda_0/k$ )
0	0.01	0	1	0

14	1743565824	2.64	1762388776	0.377

One can proceed in this way for more values of k until  $t_0$  is less than 1 (from 4.12), In a similar manner tables can be formed for other values of n., Tables to find the values of  $t_1$  corresponding to different values of k and n:

**Table-4**  
**Table to find the values of  $t_1$  corresponding to different values of k and n=1**

When n=1				
Values of k	Values of R.H.S. of (4.15a)	Values of m (= $kt_1/\lambda_0$ ) for which L.H.S. is just > R.H.S.	Values of L.H.S. which is just > R.H.S.	Values of $t_1$ (= $m\lambda_0/k$ )
0	0.01	1	0.135	$\infty$
1	0.01	1	0.27	2
2	0.02	1	0.541	1

In this case we can not proceed farther because for other values of k the values of  $t_1$  will be less than 1. But  $t_1$  can not be <1 by 4.12.

**Table-5**  
**Table to find the values of  $t_1$  corresponding to different values of k and n=2**

When n=2				
Values of k	Values of R.H.S. of (4.15a)	Values of m (= $kt_1/\lambda_0$ ) for which L.H.S. is just > R.H.S.	Values of L.H.S. which is just > R.H.S.	Values of $t_1$ (= $m\lambda_0/k$ )
0	0.015	2	0.018	$\infty$
1	0.015	2	0.073	4
2	0.03	1.99	0.5890	1.99
3	0.09	2	1.17	1.33
4	0.36	2	4.688	1

In this case we cannot proceed farther because for other values of k the values of  $t_1$  will be less than 1. But  $t_1$  cannot be <1 by 4.12.

**Table-6**  
**Table to find the values of  $t_1$  corresponding to different values of  $k$  and  $n=3$**

When $n=3$				
Values of $k$	Values of R.H.S. of (4.15a)	Values of $m (= kt_1/\lambda_0)$ for which L.H.S. is just $>$ R.H.S.	Values of L.H.S. which is just $>$ R.H.S.	Values of $t_1 (= m\lambda_0/k)$
0	0.02	2.99	0.09	$\infty$
1	0.02	2.99	0.0299	5.98
2	0.04	2.99	0.1797	2.99
3	0.12	3	0.535	2
4	0.48	3	3.212	1.5
5	2.4	3	19.27	1.2
6	14.4	3	115.65	1

In this case we cannot proceed farther because for other values of  $k$  the values of  $t_1$  will be less than 1. But  $t_1$  cannot be  $< 1$  by 4.12. [L.H.S. = Left Hand Side; R.H.S. = Right Hand Side], Hence from tables (Table-1 to Table-6) one can easily get the values of  $t_0$  and  $t_1$  for different values of  $k$  and  $n$ . And hence decision regarding 4.13 can be taken. The following subsection contains the corresponding R program.

**R program used for finding values of  $t_0$  and  $t_1$**

```
n=2;alpha=0.01 # Taking n=2; the same program will run for n=1, n=3 and so on.
k=seq(0,14,by=1) # For computation purpose k=0 to 14 has been taken. More values can be taken.
product=0
for(i in 1:26)
{
    product[i]=(factorial(k[i]))*(n+1)*(alpha/2)
}
product # product symbolises the R.H.S of (4.15a) and (4.15b) for different values of k
lamda.not=2
mm=k/lamda.not #Here mm= k/lambda_0 for different values of k.

## PROGRAM FOR (4.15a) i.e. TO FIND THE VALUES OF t_0 ##
##### PROGRAM TO BE DONE TAKING k=0 #####
m=0
m[1]=0
s1=(exp((-lamda.not*m[1]))*(lamda.not*m[1])^k[1]
# [In this program s1 is the expression given under summation in the L.H.S. of (4.15a) for k=0]
##### PROGRAM TO BE DONE MANY TIMES CHANGING THE VALUES OF "k" #####
s=0
s[1]=(exp((-lamda.not*m[1]))*(lamda.not*m[1])^k[15]
for(i in 2:300){
    m[2]=0.01
    s[i]=(exp((-lamda.not*m[i]))*(lamda.not*m[i])^k[15]
    m[i+1]=m[i]+0.01
}
product[15];mm[15]
sum=0
sum[1]=s[1]
for(i in 2:300){
    sum[i]=sum[i-1]+s[i]
}
sum
## PROGRAM FOR (4.15b) i.e. TO FIND THE VALUES OF t_1 ##
##### PROGRAM TO BE DONE TAKING k=0 #####

m1=0 # Here m1 is equivalent to m (as used in (4.15b))
m1[1]=n
```

$s2 = (\exp(-\lambda \cdot m1[1])) \cdot (\lambda \cdot m1[1])^k$  # if necessary, this line has to be run many times for different values of  $m$ , by 'for loop'  
# [In this program  $s2$  is the expression given under summation in the L.H.S. of (4.15a) for  $k=0$ ]

```
##### PROGRAM TO BE DONE MANY TIMES CHANGING THE VALUES OF "k" #####
ss=0
ss[1]=(exp((-lamda.not*m1[1]))*(lamda.not*m1[1])^k[5])
for(i in 2:100)
{
m1[2]=m1[1]-0.01
ss[i]=(exp((-lamda.not*m1[i]))*(lamda.not*m1[i])^k[5])
m1[i+1]=m1[i]-0.01
}
product[5];mm[5]
sum1=0
sum1[1]=ss[1]
for(i in 2:100)
{
sum1[i]=sum1[i-1]+ss[i]
}
sum1
```

## Conclusion

In this paper a test procedure for Curved Poisson distribution has been found out. Here Uniform distribution has been used as the distribution involved in Poisson distribution. One may use other discrete distributions in place of Uniform distribution also and plenty of scopes are there for doing further research. This paper hopes the test procedure will help to take decision about a data that follow Curved Poisson distribution.
