#### Abstract

Mass loss and thermometric methods have been used to study the inhibition of mild steel corrosion in HCl and  $H_2SO_4$  solution by the pyridyl substituted thiourea compound 1-(2,6-diazene)–3–benzyl thiourea  $(ST_1)$ , 1–(3'-pyridyl) – 3 – benzyl thiourea  $(ST_2)$ , 1 – (3'- pyridyl) – 1 –phenyl thiourea  $(ST_3)$ , 1–(2'- pyridyl)–3–phenyl thiourea  $(ST_4)$ . Values of inhibition efficiency obtained from the two methods are in good agreement with each other and are dependent upon the concentration of inhibitor and acid. The difference in the inhibition behaviour of the compounds have been explained in terms of the solubility of the substituted thiourea compounds and strength of the inhibitor-metal bond. Inhibition efficiency of all inhibitors increas with increasing concentration of inhibitor. Inhibition efficiency is more in case of  $H_2SO_4$  rather than in HCl. Inhibition efficiency was found maximum upto 99.26% for mild steel in  $H_2SO_4$  solution. Inhibition efficiencies of synthesised substituted thiourea have been found much more than their parent thiourea.

Keywords: Corrosion inhibition, weight loss method, thermometric method, surface coverage, corrosion rate etc.

### Introduction

Mild steel finds a variety of applications industrially, for mechanical and structural purposes, like bridge work, building, boiler plates, steam engine parts and automobiles. It finds various uses in most of the chemical industries due to its low cost and easy availability for fabrication of various reaction vessels, tanks, pipes etc. Since it suffers from severe corrosion in aggressive environment, it has to be protected acids like HCl and  $H_2SO_4$  have been used for drilling operations, pickling baths and in decaling processes.

Corrosion of mild steel and its alloys in different acid media have been extensively studied<sup>1-4</sup>. It has been reported<sup>5-6</sup> that addition of certain organic compounds bearing hetero atoms, retards the corrosion of mild steel in acidic environments. Recently considerable interest has been generated in the use of nitrogen, oxygen and sulphur containing organic compounds as corrosion inhibitor for mild steel in different acids<sup>7-8</sup>.

Organic compounds having hetero atoms atoms like O, N, S and in some cases Se, are found to have higher basicity and electron density. Thus to help corrosion inhibition<sup>9</sup>, O, N and S are the active centres for the process of adsorption on the metal surface<sup>10-15</sup>. The electric charge, orientation, shape and size of the molecule play an important role on the effectiveness of inhibition. Efficiency of their inhibitory effect depends upon the basicity of these atoms<sup>16-18</sup>.

Among these, thiourea and its derivatives have been investigated extensively. These are polar molecules in which

S atom having permanent –ve charge and N atom have +ve charge. As the molecule approaches the electrode surface the electric field of double layer increases the polarization of molecule and induces additional charges on S and N atoms, a condition that enhance the adsorption of molecule.

In the present study an attempt has been made to study the influence of varying concentration of substituted thiourea viz.  $(ST_1, ST_2, ST_3, ST_4)$  on corrosion of mild steel in different concentration of hydrochloric acid, sulphuric acid employing mass loss and thermometric method.

## **Material and Methods**

Mild steel specimens of composition 99.3% Fe, 0.2% C, 0.3% Mg, 0.14% Si and 0.04% S of size 2.00 cm  $\times 2.00$  cm  $\times 0.03$  cm were used for the complete immersion test. All the specimens were polished by buffing and rubbing with emery paper to obtain mirror like finishing. The solution of HCl were prepared by using double distilled water. All chemicals used were of AR grade.

Each specimen was suspended by a V-shaped glass hook made by capillary tubes and immersed in a glass beaker containing 50 mL of the test solution at room temperature, after the test specimen was cleaned with benzene and then dried with hot air dryer. The percentage efficiency was calculated as<sup>19</sup>

$$\eta \% = 100 \ \underline{(\Delta W_u - \Delta W_i)}_{\Delta W_u}$$

where  $\Delta W_u$  and  $\Delta W_i$  are the weight loss of the metal in uninhibited and inhibited solution, respectively. Inhibition efficiency were also calculated using a thermometric method. This involve the immersion of single specimen of measurement 2.00 × 2.00 × 0.03 cm in a reaction insulating chamber having 50 mL of solution at an initial room temperature. Temperature changes were measured at regular intervals using a thermometer with a precision of 0.1°C. The increase in temperature was initially slow then rapid and attained a maximum value and then decreased. The maximum temperature was noted. Percentage inhibition efficiency was calculated as<sup>20</sup>

$$\eta \% = \frac{100 (RN_f - RN_i)}{RN_f}$$

where  $RN_f$  and  $RN_i$  are the reaction number in the free

solution and in presence of inhibitor. RN is defined as

$$RN = \frac{(T_m - T_i)}{t}$$

where Tm and Ti are maximum and initial temperature, respectively and t is the time in minutes required to attain maximum temperature. The corrosion rate (CR) in mm/yr can be obtained by the following equation<sup>21</sup>

Corrosion rate (mm / yr) = 
$$\frac{\Delta W \times 87.6}{A \times T \times d}$$

where,  $\Delta W$  is weight loss in mg, A is area of specimen in cm<sup>2</sup>, T is time of exposure in hours, d is density of metal in gm/cm<sup>3</sup> ( $\theta$ ) can be calculated as<sup>22</sup>

$$\theta = \frac{(\Delta W_u - \Delta W_i)}{\Delta W_u}$$

where  $\Delta W_u$  and  $\Delta W_i$  are the weight loss of the metal in uninhibited and in inhibited solution, respectively.

### **Results and Discussion**

Weight Loss Method: Weight loss, percentage inhibition efficiencies, corrosion rate and surface coverage for different concentration of HCl and inhibitor are given in table-1 and for different concentration of H<sub>2</sub>SO<sub>4</sub> and inhibitors are given in table-2. It can be seen from the both the tables that inhibition efficiency of inhibitor increases with increasing concentration of inhibitor. Inhibition efficiency also increases with increasing concentration of acid and all the inhibitors show maximum inhibition efficiency at the highest concentration of acids used i.e. 2.5 N HCl and 2.5 NH<sub>2</sub>SO<sub>4</sub>. The maximum inhibition efficiency was obtained for  $(ST_1)$  at an inhibitor concentration of 0.8% in 2.5 N HCl and 2.5 N H<sub>2</sub>SO<sub>4</sub> i.e. 98.48% and 99.26%, respectively. These results substituted thiourea show more inhibition show that efficiency in H<sub>2</sub>SO<sub>4</sub> than in HCl. The variation of percentage inhibition efficiency with inhibitor concentration are depicted graphically in figure 1 for HCl and in figure 2 for H<sub>2</sub>SO<sub>4</sub>. Figures show a linear curve of percentage inhibition efficiency with the concentration of inhibitor, indicating that the inhibition efficiency increases with increasing inhibitor concentration.

Thermometric Method: Inhibition efficiency values were also determined by the thermometric method. Temperature changes for mild steel in 2N, 3N and 4N sulphuric acid and hydrochloric acid solution were recorded with various inhibitor concentration. However no significant temperature changes were measured in the acid concentration of 1N HCl and H<sub>2</sub>SO<sub>4</sub> solution. Results obtained are dipicted in table 3 for HCl and table - 4 for H<sub>2</sub>SO<sub>4</sub>. The results obtained are in good agreement with those from weight loss experiments. Inhibition efficiency increases with increasing acid concentration. The variation of reaction number with inhibitor concentration, presented graphically in figure 3 for HCl and in figure 4 for H<sub>2</sub>SO<sub>4</sub> shows linear behaviour with positive slope, indicating that the reaction number increase with increasing acid concentration it decreases with increasing inhibitor concentration. Generally, the Inhibitor having oxygen, nitrogen and sulphur atoms responsible for the adsorption on metallic surface. This process may block active sides, hence may decrease the corrosion rate. Adsorption plays an important role in the inhibition of metallic corrosion by organic inhibitors. Many investigators have used the Langmuir adsorption isotherm to study inhibitor characteristics. Assuming that the inhibitors adsorbed on the metal surface decrease the surface are available for cathodic and anodic reactions to take place. Hoar and Holliday have shown that the Langmuir isotherm

 $\log \left[ \theta / (1 - \theta) = \log A + \log C - (\theta / 2.3 \text{ RT}) \right]$ 

should give a straight line of unit gradient for the plot of  $\log[\theta / (1 - \theta)]$  versus log C, where surface coverage  $\theta$  is calculated as  $(RN_f - RN)/RN_f$ . A is a temperature independent constant, and C is the bulk concentration of the inhibitor (mol L<sup>-1</sup>)

The corresponding plots, shown in figure 5 and 6 are linear, but the gradients are not equal to unity as would be expected for the ideal Langmuir adsorption isothem equation.

It has also been observed that the efficiency is higher in higher concentration of HCl and H<sub>2</sub>SO<sub>4</sub>. This may be because of the fact that the inhibitor ionize more readily under more acid strength and is absorbed more easily on the surface of metal. Acids which have more dissociation constant i.e. higher values of Ka or lower values of pKa like HCl and H<sub>2</sub>SO<sub>4</sub> enhance the ionization of thiourea thus causes more adsorption of substituted thiourea on metal surface. Therefore they act as better inhibitor at higher concentrations. Adsorption plays an important role in the inhibition of metallic corrosion by organic inhibitors. The efficiencies of inhibitors expressed as the relative reduction in corrosion rate can be quantitatively related to the amount of adsorbed inhibitors on the metal surface. It is assumed, that the corrosion reaction are prevented from occuring over the active sites of the metal surface covered by adsorbed inhibitors species, whereas the corrosion reaction occurs normally on the surface at inhibitors free area.

Figure-5 Langmuir adsorption isotherms for mild steel in 2.5N HCl with inhibitor addition

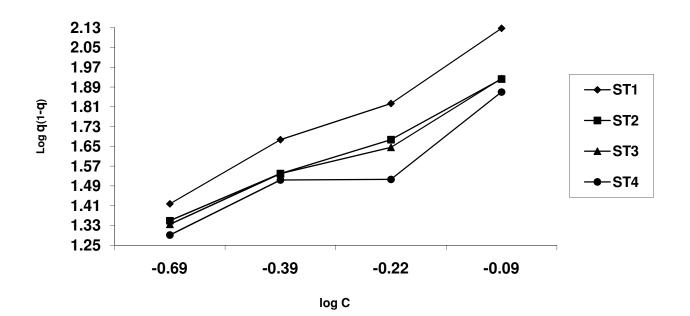

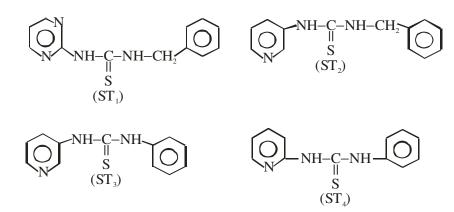

Figure-6 Langmuir adsorption isotherms for mild steel in 2.5N H<sub>2</sub>SO<sub>4</sub> with inhibitor additions ST<sub>1</sub>: 1-(2, 6-diazene) – 3 –benzyl thiourea, ST<sub>2</sub>: 1 - (3' pyridyl) – 3 – benzyl thiourea, ST<sub>3</sub>: 1 – (3' - pyridyl) – 1 –phenyl thiourea, ST<sub>4</sub>: 1 – (2' - pyridyl) – 3 –phenyl thiourea

The results revealed that thiourea compounds effectively reduce the corrosion rates of mild steel in acid solution. The following order of inhibition efficiency has been observed for the four substituted thiourea for Mild Steel  $ST_4 < ST_3 < ST_2 < ST_1$ .

Organic compounds absorb on the metal surface forming a barrier between the metal and the corrosive environment. Some structural features of the organic compounds help them to do so. The lone pair electrons of the mentioned atoms facilitate the adsorption process.  $ST_1$  is most effective inhibitor since lone pair of electron present on nitrogen atoms of pyrimidine ring and thiourea moiety is maximum.  $ST_2$  has pyridyl ring having less electron density in comparision to  $ST_1$  hence it is less basic than  $ST_1$ . In case  $ST_3$  and  $ST_4$  lone pair present on nitrogen atoms attached to benzene take part in the resonance. Hence they are less available for bonding with metal surface.

The substituted thiourea possess N and S as hetero atom and thereby offering a electron rich reaction centre. It has been reported that inhibitors are adsorbed on corroding metal surface through electron rich N and S atom thus forming a chemisorbed monolayer of the inhibitor which act as physical barrier between the metal and corrosive solution.

The higher ionization of substituted thiourea in  $H_2SO_4$  than in HCl may be the reason of these compound exhibiting higher inhibition efficiencies in  $H_2SO_4$  as compared in HCl since increased ionisation of inhibitor molecule will facilitate the adsorption of inhibitor on the Mild Steel surface.

The inhibition efficiency is thus, directly proportional to the fraction of the surface covered with adsorbed inhibitors.

### Conclusion

A study of pyridyl substituted thiourea compounds ( $ST_1$ ,  $ST_2$ ,  $ST_3$ ,  $ST_4$ ) are efficient inhibitors of corrosion of mild steel in sulphuric acid and hydrochloric acid. Both mass loss and thermometric methods has shown that the inhibition efficiency of four inhibitors increases with increasing in

concentration of inhibitor and increases as increasing the concentration of HCl and  $H_2SO_4$ . The highest inhibitor efficiency upto 98.48% in 2.5 N HCl and 99.26% in 2.5 N  $H_2SO_4$ .

The corrosion rate of mild steel is maximum in HCl. The corrosion rate is governed by number of complex reactions taking place and also the nature of the protective film. Finally it may be concluded from the results that the newly synthesised pyridyl substituted thiourea are efficient corrosion inhibitor for mild steel in  $H_2SO_4$  and HCl.

The inhibition of the compound is governed by chemisorption mechanism in both the acid media. As the molecule approaches the electrode surface the electric field of double layer increase the polarization of molecules and induces additional charges on S and N atom and thus enhances the adsorption of molecules.
